

Record Rare Earths Grades at Monte Alto Project

- Record ultra-high-grade rare earths grades at Monte Alto of up to **45.7% Total Rare Earth Oxide (TREO)**
- Exceptional rare earths **NdPr** grades up to **69,558 ppm (6.96%)** and heavy rare earths **DyTb** grades of up to **11,696 ppm (1.17%)**
- High-grade assays of up to **17,029 ppm (1.7%) niobium oxide (Nb₂O₅)**, **382 ppm scandium oxide (Sc₂O₃)**, **962 ppm tantalum oxide (Ta₂O₅)**, and **5,781 ppm uranium oxide (U₃O₈)**
- New drilling results confirm the continuity and scale of the ultra-high-grade REE-Nb-Sc-Ta-U mineralised envelope, that remains open along strike and at depth
- High-grade rare earths monazite-sand results include **18m at 6.8% TREO, from surface**

Significant intercepts from the latest Monte Alto diamond drilling results include:

- **37m at 16.1% TREO** from 10m, with 23,476 ppm NdPr, 1,157 ppm DyTb, 4,637 ppm Nb₂O₅, 108 ppm Sc₂O₃, 316 ppm Ta₂O₅, and 1,965 ppm U₃O₈ (MADD0101), including:
 - **29m at 18.5% TREO** from 10m, with 27,071 ppm NdPr, 1,293 ppm DyTb, 5,127 ppm Nb₂O₅, 122 ppm Sc₂O₃, 350 ppm Ta₂O₅, and 2,205 ppm U₃O₈ (MADD0101), including:
 - **7.1m at 35% TREO** from 21.9m, with 56,681 ppm NdPr, 2,522 ppm DyTb, 8,628 ppm Nb₂O₅, 237 ppm Sc₂O₃, 582 ppm Ta₂O₅, and 4,063 ppm U₃O₈ (MADD0101)
- **38.8m at 16% TREO** from 121m, with 25,978 ppm NdPr, 1,319 ppm DyTb, 4,302 ppm Nb₂O₅, 150 ppm Sc₂O₃, 299 ppm Ta₂O₅, and 2,052 ppm U₃O₈ (MADD0115), including:
 - **19.2m at 27% TREO** from 131.1m, with 44,120 ppm NdPr, 2,234 ppm DyTb, 7,224 ppm Nb₂O₅, 224 ppm Sc₂O₃, 494 ppm Ta₂O₅, and 3,279 ppm U₃O₈ (MADD0115)
- **7.8m at 22.7% TREO** from 86.2m, with 37,118 ppm NdPr, 1,943 ppm DyTb, 6,715 ppm Nb₂O₅, 212 ppm Sc₂O₃, 432 ppm Ta₂O₅, and 2,982 ppm U₃O₈ (MADD0110), including:
 - **3.8m at 31.2% TREO** from 86.2m with 52,095 ppm NdPr, 2,713 ppm DyTb, 9,469 ppm Nb₂O₅, 222 ppm Sc₂O₃, 585 ppm Ta₂O₅, and 3,707 ppm U₃O₈ (MADD0110)
- **14m at 21.3% TREO** from 236m, with 36,381 ppm NdPr, 1,820 ppm DyTb, 5,921 ppm Nb₂O₅, 150 ppm Sc₂O₃, 370 ppm Ta₂O₅, and 2,643 ppm U₃O₈ (MADD0106), including:
 - **6.4m at 28.9% TREO** from 243m, with 49,810 ppm NdPr, 2,487 ppm DyTb, 8,158 ppm Nb₂O₅, 179 ppm Sc₂O₃, 509 ppm Ta₂O₅, and 3,467 ppm U₃O₈ (MADD0106)
- **20m at 15.8% TREO** from 118m, with 25,777 ppm NdPr, 1,190 ppm DyTb, 4,054 ppm Nb₂O₅, 190 ppm Sc₂O₃, 261 ppm Ta₂O₅ and 2,297 ppm U₃O₈ (MADD0069)
- **15m at 16.4% TREO** from 60m, with 27,907 ppm NdPr, 1,458 ppm DyTb, 4,963 ppm Nb₂O₅, 152 ppm Sc₂O₃, 314 ppm Ta₂O₅, and 2,172 ppm U₃O₈ (MADD0040)
- **15.7m at 15.8% TREO** from 236.9m, with 26,481 ppm NdPr, 1,262 ppm DyTb, 4,431 ppm Nb₂O₅, 135 ppm Sc₂O₃, 271 ppm Ta₂O₅, and 1,938 ppm U₃O₈ (MADD0139)

- **13m at 15.5% TREO** from 10m, with 26,763 ppm NdPr, 1,325 ppm DyTb, 4,480 ppm Nb₂O₅, 117 ppm Sc₂O₃, 283 ppm Ta₂O₅, and 1,744 ppm U₃O₈ (MADD0138)
 - **10.4m at 16% TREO** from 108.3m, with 26,850 ppm NdPr, 1,378 ppm DyTb, 4,542 ppm Nb₂O₅, 169 ppm Sc₂O₃, 285 ppm Ta₂O₅, and 2,201 ppm U₃O₈ (MADD0047)
-

Brazilian Rare Earths' CEO and Managing Director, Bernardo da Veiga, commented:

"Less than a year ago, we announced the first drill 'discovery' of ultra-high-grade REE-Nb-Sc-Ta-U mineralisation at Monte Alto.

Today, we are pleased to report new drilling results that include some of the highest grades ever reported globally, including exceptional rare earths grades of up to 45.7% TREO. These outstanding drilling results confirm Monte Alto's position as one of the highest grade rare earths and critical minerals projects in the world.

Since the breakthrough discovery of Monte Alto, our exploration team has completed a total of 22,658 metres of diamond drilling. Notably, the Monte Alto deposit remains open along strike and at depth for high-grade rare earths, niobium, tantalum, scandium, and uranium mineralisation. The scale and continuity of the high-grade mineralisation provides a strong foundation for an updated JORC resource estimate, which is expected in the second quarter of 2025.

Finally, the potential for district-scale exploration and development near Monte Alto is unrivalled. Our recent discoveries, within ~4 km of the main deposit, underpin a compelling exploration opportunity for new ultra-high-grade REE-Nb-Sc-Ta-U discoveries."

Brazilian Rare Earths Limited (ASX: BRE) (OTCQX: BRELY / OTCQX: BRETf) is pleased to report a major set of assay results from diamond drilling at the **Monte Alto Rare Earths Project** (Monte Alto), located in Bahia, Brazil.

The world-class Monte Alto project is hosted within the Volta do Rio Plutonic Suite (VRPS), a large-scale magmatic system that extends over 180 km in Bahia, Brazil. **Brazilian Rare Earths (BRE)** holds a dominant land position across the VRPS, which holds exceptional exploration potential for new discoveries of ultra-high-grade mineralisation, including rare earth elements (REE), niobium (Nb), scandium (Sc), tantalum (Ta), and uranium (U). BRE's key exploration projects within this province include the Monte Alto, Sulista and Pelé projects.

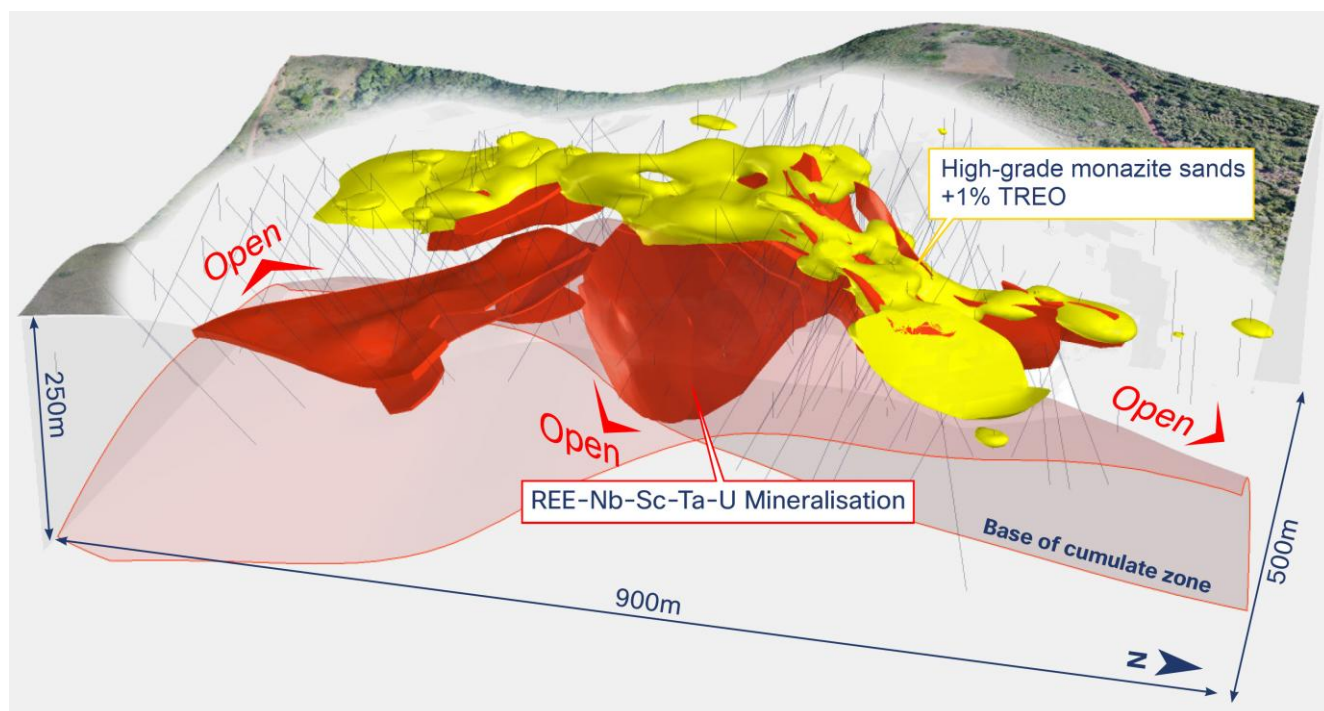

Figure 1: Monte Alto deposit with high-grade monazite sands overlaying the hard rock REE-Nb-Sc-Ta-U mineralisation – Oblique View to the Southwest

The latest diamond drilling results successfully expanded the Monte Alto deposit envelopes, confirming the three-dimensional continuity of high-grade REE-Nb-Sc-Ta-U mineralisation and monazite-sand deposits (Figure 1). The new drilling results also delineated a series of stacked, continuous ultra-high-grade horizons of REE-Nb-Sc-Ta-U mineralisation across a geological fold that connects the southern and northern domains of the Monte Alto deposit.

Monte Alto's chevkinite and apatite-britholite REE-Nb-Sc-Ta-U mineralisation is unrivalled, with no deposits of comparable scale and grade identified from publicly available information and reviewed research papers.

Successful Drilling Results

The new drilling assays are from 69 diamond core holes totalling 10,412 metres. Results from 32 drill holes totalling 5,093 metres have been previously reported. Assays are pending for a further 18 diamond core holes totalling 3,011 metres.

Exceptional rare earths grades of up to 45.7% TREO¹ were returned from the latest drilling, which is now the highest grade rare earths assay at Monte Alto so far. Ultra-high grades of neodymium and praseodymium of up

¹ TREO = Total Rare Earth Oxides; NdPr = Nd₂O₃ + Pr₆O₁₁; DyTb = Dy₂O₃ + Tb₄O₇

to 69,558 ppm NdPr¹ and exceptional heavy rare earths grades of dysprosium and terbium of up to 11,696 ppm DyTb¹ were intersected in the drill results.

In addition to these ultra-high rare earths grade assays, drilling results also set a new project record niobium grade of 1.7% Nb₂O₅, scandium grades of up to 382 ppm Sc₂O₃, tantalum grades of up to 962 ppm Ta₂O₅ and uranium grades of up to 5,781 ppm U₃O₈.

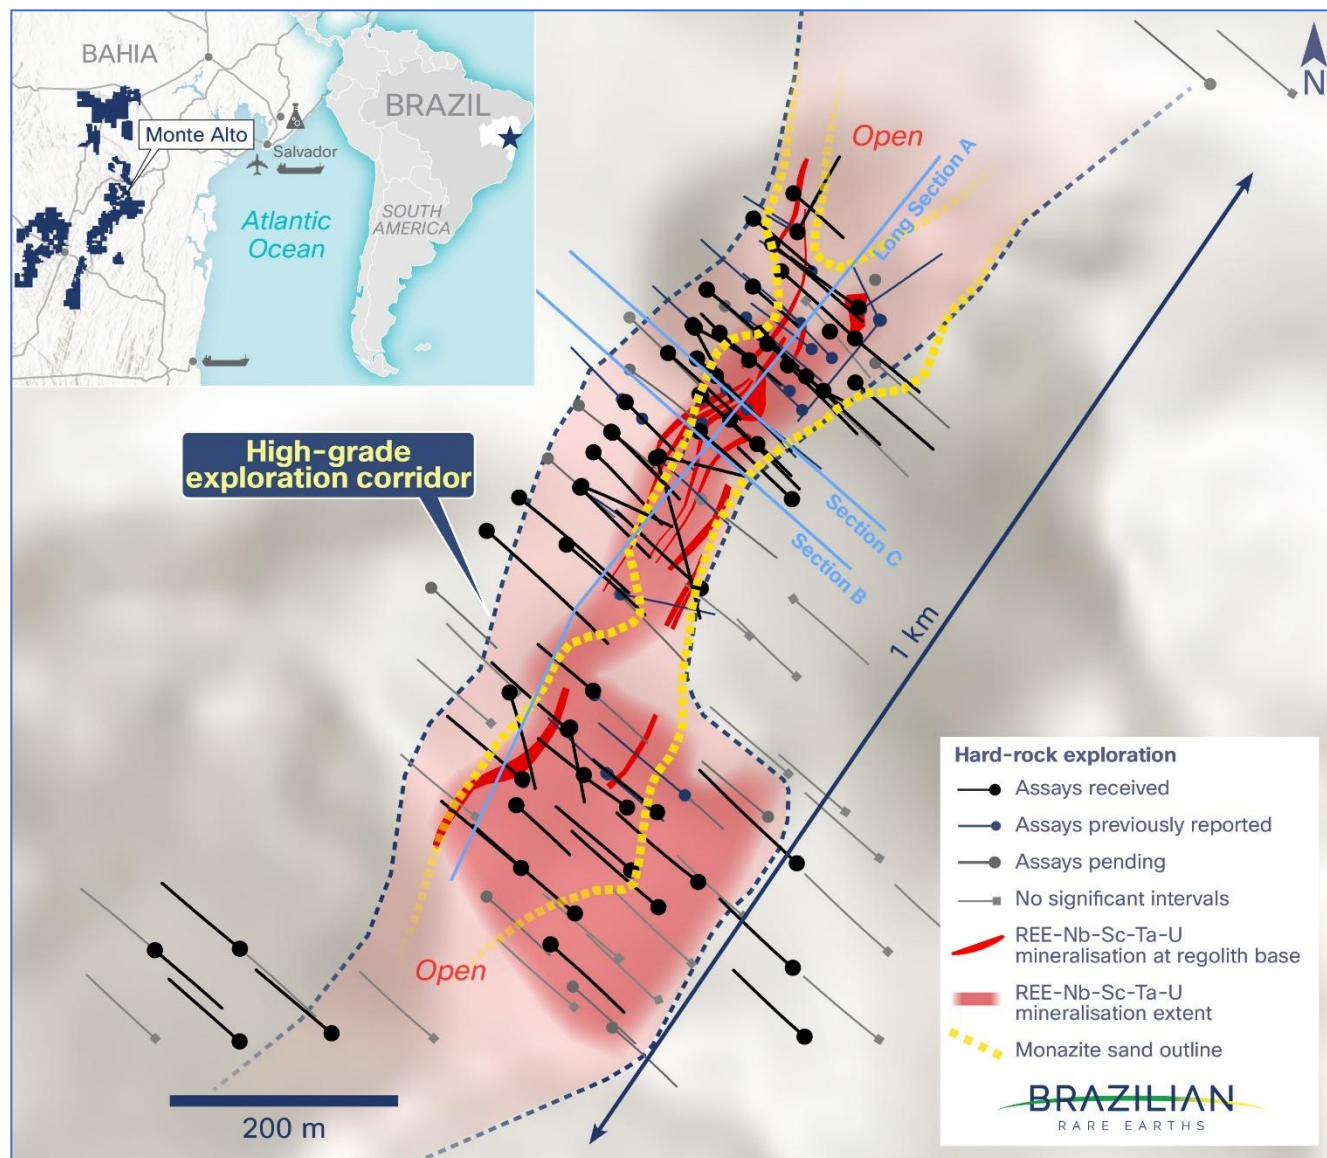

Figure 2: Monte Alto Drilling Corridor²

Targeted in-fill diamond drilling successfully enhanced the geological interpretation of the deposit and improved confidence in the continuity of grade, which will underpin the upcoming mineral resource estimate in Q2 2025.

At the boundary of the Monte Alto deposit, a limited number of drill holes were completed for geological and geotechnical assessment. These include 4 new drill holes in this announcement, plus 27 historical holes, totalling 4,141 metres.

² Refer ASX Announcements dated 1 February 2024 and 26 August 2024 (Original ASX Announcements) for details of previously reported exploration results. BRE is not aware of any new information or data that materially affects the information included in the Original ASX Announcements.

Shallow and stacked ultra-high-grade REE-Nb-Sc-Ta-U mineralisation

The latest drill holes intersected a series of stacked, thick intervals of high-grade (+10% TREO) and ultra-high-grade (+15% TREO) REE-Nb-Sc-Ta-U mineralisation from shallow depths.

The best exploration result was diamond drill hole MADD0101, a continuous 28.8 metres (true-width) ultra-high-grade 18.5% TREO intercept starting from just 10 metres of depth. This wide drill intercept was contained within a combined 36.7m intercept of 16.1% TREO, from 10 metres of depth (see Figure 3).

This shallow ultra-high-grade REE-Nb-Sc-Ta-U mineralisation occurs in stacked, closely spaced horizons of weathered, free-dig mineralisation. These stacked horizons are gently dipping, supporting potential low-strip ratio resources. Deeper hard rock intercepts include 4.7m at 14.9% TREO (MADD010)³ and 7.8m at 22% TREO (MADD010)³. These new results highlight that the combined true thickness of regolith and hard rock mineralisation exceeds 40 metres at the centre of Monte Alto.

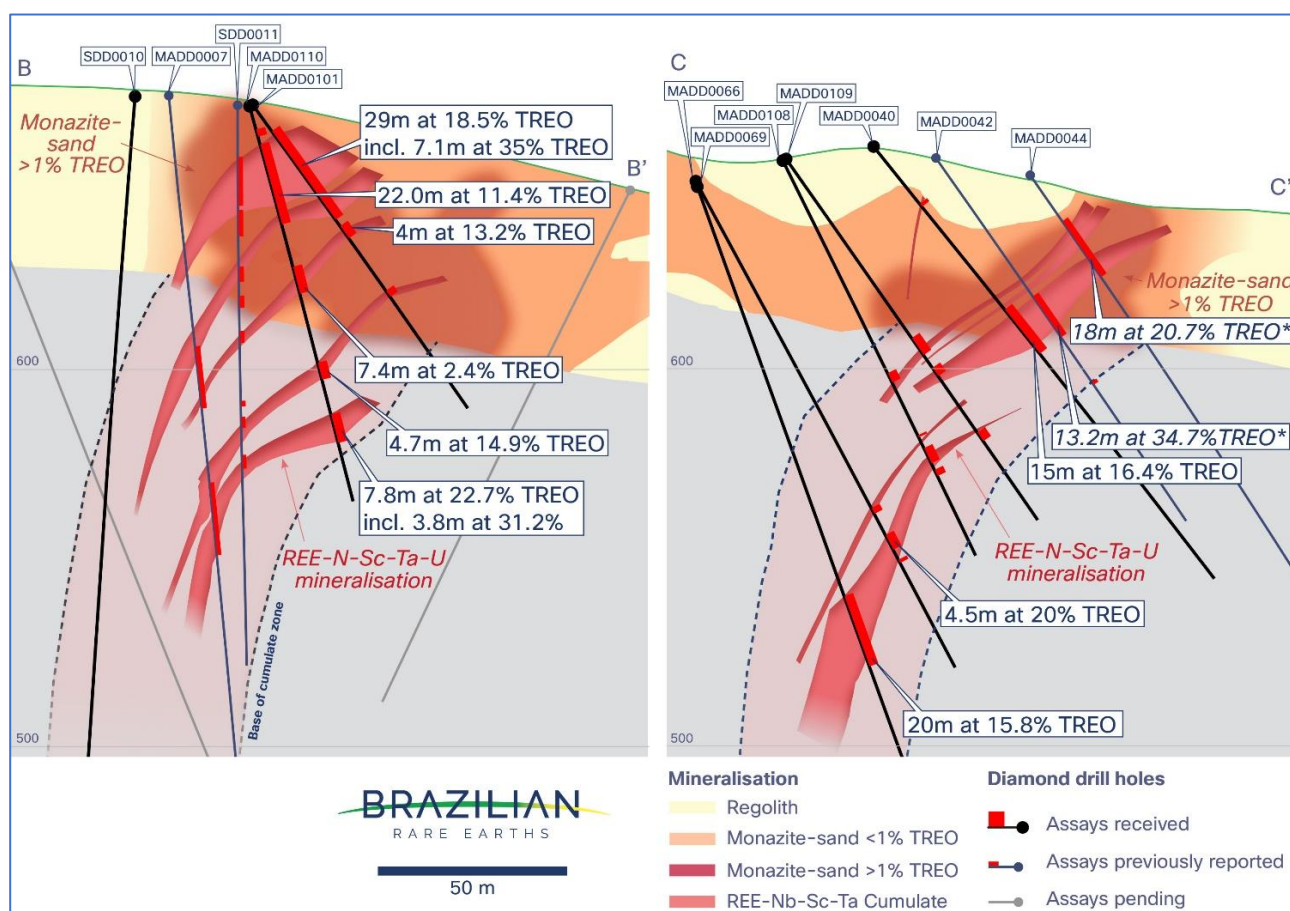

Figure 3: Cross section view to the northeast at the southern end of Monte Alto - highlighting multiple stacked high-grade REE-Nb-Sc-Ta-U horizons, below the high-grade monazite-sand cap.

**Previously reported assays are in italics.⁴*

Increasing grade, continuity and scale at depth

The latest drill results increase the confidence in geological and grade continuity across the Monte Alto deposit. Deeper drill holes significantly extended continuous horizons of thick and ultra-high-grade REE-Nb-Sc-Ta-U mineralisation at the centre of the Monte Alto deposit. The new drill results also in-filled a previous exploration gap between the southern and central portions of the Monte Alto deposit (see Figure 4).

Northwest of the centre of the Monte Alto deposit, a new intercept of 15m at 16.4% TREO from 60 metres (MADD0040) confirmed the down-dip continuation of ultra-high-grade near-surface mineralisation (13.2m at 34.7% TREO), intercepted in a previously reported drill hole MADD0043.⁵ The cumulate horizon continues at depth, with results including 20m at 15.8% TREO from 118 metres (MADD0069), that intersected an ultra-high-grade mineralized zone ~80 metres below the base of the overlying high-grade monazite-sand deposit.

New drill hole assays across the northwest and southeast of the Monte Alto centre, increased the continuity of high-grade mineralisation at depth throughout the deposit. Highlights include 19m at 27% TREO (MADD0115), 15.3m at 12.3% TREO (MADD0114), and 10.5m at 14.3% TREO (MADD0120). These intercepts verified the continuity of a major, high-grade REE-Nb-Sc-Ta-U cumulate horizon that extends along the length of the Monte Alto deposit. This REE-Nb-Sc-Ta-U cumulate horizon extends to the south-west to the previously reported hole MADD0099, which returned an exceptional ultra-high-grade intercept of 47.1m downhole at 19.6% TREO.⁵

Further to the southwest, the REE-Nb-Sc-Ta-U cumulate zone was successfully extended by an extra 200m down-plunge where the deposit remains open. Ultra-high-grades of rare earths were recorded in drill holes MADD0106 (14m at 21.3% TREO), MADD0116 (8m at 15.2% TREO), and MADD0139 (15.7m at 15.8% TREO).

The results of these new drill holes also define near-continuous horizons of cumulate mineralisation that extend from outcropping mineralisation in the northwest of Monte Alto (where previously reported ultra-high-grade boulder samples averaged 32.7% TREO⁶ to ~550m down-plunge to the southeast. This cumulate mineralisation now extends ~250m below surface and remains open at depth.

The southward projection of the cumulate horizon bridges an existing exploration gap between the southern and northern parts of the Monte Alto deposit. The combined drill-tested strike length of the cumulate zone at the Monte Alto deposit measures ~700m, extending from the recently discovered near-surface ultra-high-grade zone of 13m at 15.5% TREO (including 6.9m at 25.7%, MADD0138) at the northern end of the deposit, to a mineralised zone of 5.9m at 9.3% TREO (MADD0026) southwestward. Cumulate REE-Nb-Sc-Ta-U mineralisation remains open to the north and south of these recent discoveries, highlighting significant potential for the Monte Alto deposit to increase in size along strike.

Results from drill hole MADD0138, located at the northern edge of the deposit, underscores the potential for a continuous horizon of mineralisation that extends an additional ~350m northward towards drill hole MADD0039. Although a modest intercept compared to other stellar Monte Alto results, MADD0039 suggests that the broad REE-Nb-Sc-Ta-U cumulate zone may extend over at least ~1 km of strike within the Monte Alto project area.

⁵ Refer ASX Announcement dated 26 August 2024 (Original ASX Announcement) for details of previously reported exploration results. BRE is not aware of any new information or data that materially affects the information included in the Original ASX Announcement.

⁶ Refer Prospectus dated 13 November 2023 released on the ASX Market Announcements Platform on 19 December 2023 (Original ASX Announcement) for details of previously reported exploration results. BRE is not aware of any new information or data that materially affects the information included in the Original ASX Announcement.

Figure 5: Ultra-high-grade core sections with chevkinite mineralisation (brown) and accessory apatite-britholite (pale flecks)

Note. NQ size core sections are from metallurgical hole DMT-0005 at 113.1m (left) and 110.9m (right). DMT-0005 twins a previously reported interval of 19.8m at 26.3% TREO from 104.2m (MADD0007)⁸.

The chevkinite and apatite-britholite cumulate horizons are interpreted as analogous to stratiform deposits of Fe-Ti-V mineralisation. These deposits may form through density-driven sorting of metal oxide-rich minerals or immiscible liquids, which segregate from a relatively buoyant, silica-rich conjugate phase within a magma chamber. Recent assay results from the deeper, less-weathered portions of the Monte Alto deposit reveal similar segregation patterns within the REE-Nb-Sc-Ta-U cumulate horizons and the surrounding granite gneiss.

Figure 7 depicts geochemical profiles from a drill intercept across the Monte Alto REE-Nb-Sc-Ta-U cumulate horizon. This chart highlights variations in critical element and whole rock oxides with increasing depth in MADD0106 drill core. At the base of the REE-Nb-Sc-Ta-U horizon, silica and alumina drop sharply from nearly 100% to less than 10%, marking a clear transition from the silicate-dominated phases to the ultra-high-grade (>15% TREO) silica-undersaturated chevkinite and apatite-britholite phases which are highly enriched in rare earths and critical element oxides. Chevkinite and apatite-britholite mineralisation forms a massive, homogeneous, ultra-high-grade cumulate layer visible in core photos in Figure 6.

⁸ Refer ASX Announcement dated 1 February 2024 (Original ASX Announcement) for details of previously reported exploration results. BRE is not aware of any new information or data that materially affects the information included in the Original ASX Announcement.

Figure 6: MADD0106: 14m at 21.3% TREO from 236m, including 6.4m at 28.9% TREO from 243m

Cumulate-style mineral deposits are particularly advantageous for geological modelling, exploration, and mining due to their predictable layered stratigraphy. At Monte Alto, this includes an ultra-high-grade zone rich in chevkinite and apatite-britholite. The deposit's homogeneity, tabular-like geometry, and consistent mineralogy provide a strong foundation for simplifying planning, mining and processing.

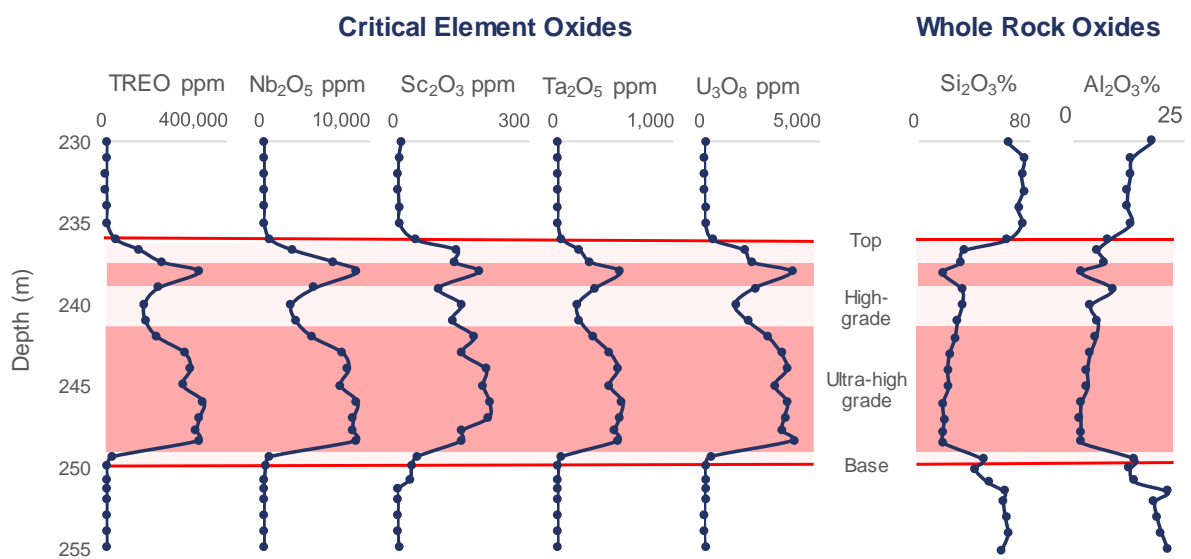

Figure 7: Critical element and whole rock oxide grades with depth across the REE-Nb-Sc-Ta-U cumulate horizon in hole MADD0106

Shallow, High-Grade, Monazite-Sand Mineralisation

Diamond drilling continued to delineate widespread horizons of high-grade monazite sand mineralisation that cover the hard rock REE-Nb-Sc-Ta-U deposit. Key intercepts from the new drilling results include:

- 18m at 6.8% TREO from surface, with 12,159ppm NdPr and 533ppm DyTb (MADD0004)
- 5m at 10.9% TREO from 26m, with 18,643ppm NdPr and 1,208ppm DyTb (MADD0128)
- 6m at 6.2% TREO from 3m, with 10,742ppm NdPr and 514ppm DyTb (MADD0025)
- 5m at 8.7% TREO from 25m, with 14,738ppm NdPr and 882ppm DyTb (MADD0125)
- 5m at 7.9% TREO from 52m, with 12,597ppm NdPr and 616ppm DyTb (MADD0128)
- 12m at 4.4% TREO from 49m, with 4,140ppm NdPr and 232ppm DyTb (MADD0035)
- 4m at 4.2% TREO from 13m, with 7,505ppm NdPr and 398ppm DyTb (MADD0048)

These shallow, high-grade intercepts represent grains of monazite contained within a weathered free-dig saprolite lithology. This is analogous to a 'mineral sands' style deposit, with valuable free-dig mineral sands available near surface for potential extraction and gravity separation.

The high-grade monazite-sand horizons extend from surface down to ~75m depth, and the higher grade (+1% TREO) zones can reach a cumulative thickness of up to ~30m.

Preliminary metallurgical test work has confirmed that the particle size distribution of the monazite grains is generally from 0.1 – 1 mm in size and can reach up to 4 mm in particle size. Metallurgical test work has demonstrated that the monazite-sands are amenable to low-cost gravity and magnetic separation processing.⁹

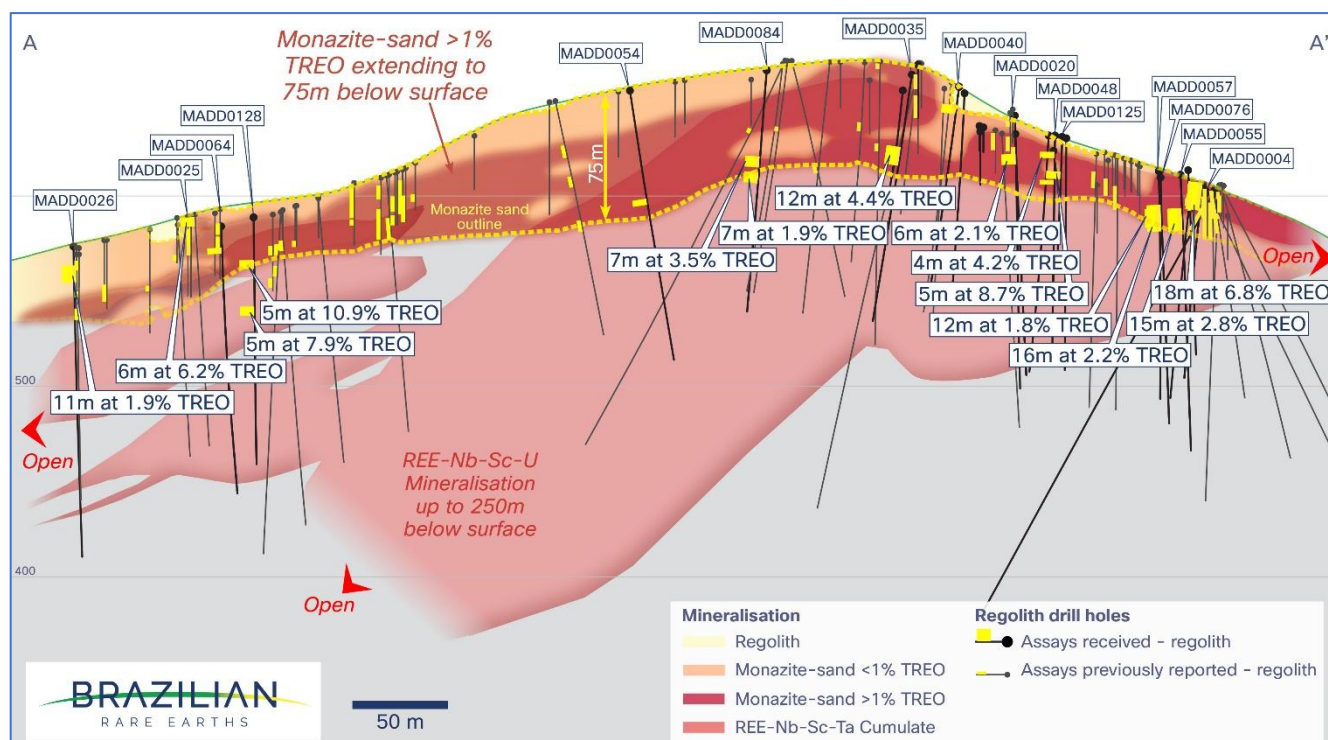

Figure 8: Long section view to the northwest of Monte Alto with latest high-grade monazite-sand intercepts

⁹ Refer Prospectus (13 Nov 2023) released on 19 Dec 2023 (Original ASX Announcement) for details of previously reported exploration results. BRE is not aware of any new information or data that materially affects the information included in the Original ASX Announcement.

Monte Alto District-Scale Exploration Opportunity

The Monte Alto project offers a compelling district-scale exploration opportunity, with a large target zone extending ~4 km from the maiden discovery deposit. The deposit's folded geometry and continuous horizon of high-grade cumulate mineralisation, suggest potential for a large, interconnected mineralised system.

Prominent magnetic anomalies trending N-S and SW (Figure 9) span the Monte Alto tenements, linking the maiden deposit to highly prospective regional rare earth exploration zones. These anomalies align with mafic cumulate horizons enriched in REE-Nb-Sc-Ta-U mineralisation.

Early exploration has already delivered exceptional results, including three significant bedrock-hosted rare earth discoveries. One standout, ~500 m west of the maiden deposit, returned a grab sample assay of 10.2% TREO (R377, previously reported)¹⁰, highlighting potential for the mineralised system to extend westward.

Further south of the Monte Alto deposit, a prominent N-S magnetic and geophysical anomaly corridor extends for over 10 km (Figure 9). Within this corridor, ~2.5 km south of the maiden deposit, a large outcrop of high-grade rare earths was discovered. Channel sampling over a ~3 m wide mineralised zone, returned grades of 10.7% TREO, including exceptional heavy rare earth grades of 7.5% HREO (previously reported).¹

These successful results highlight the exploration potential of the Monte Alto 'district' - a key focus for 2025.

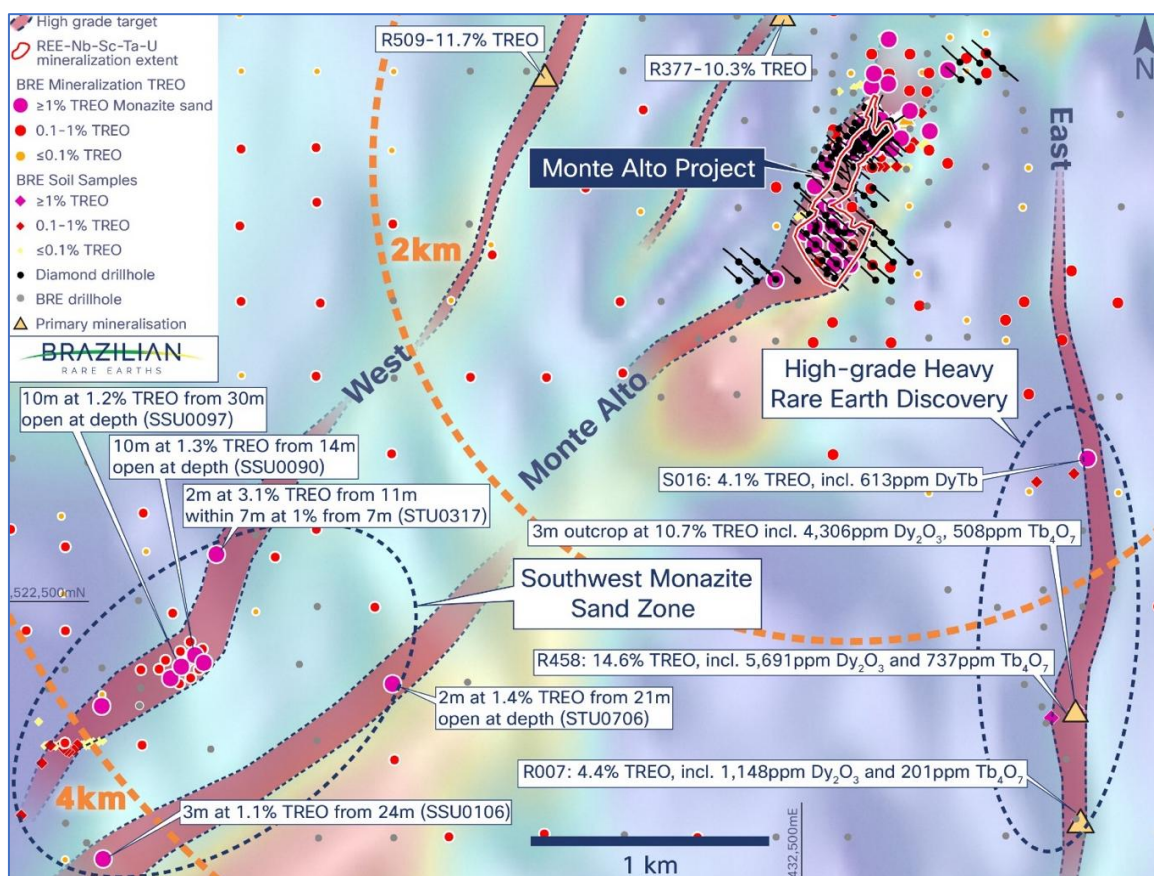

Figure 9: Monte Alto 'district-scale' rare-earth exploration corridors¹¹

Next Steps – Monte Alto

- **Magnetic and Geophysical Drone Survey:** Conduct a comprehensive drone-based magnetic and geophysical survey across the entire Monte Alto district to refine target exploration zones (Q1 2025)
- **Step-Out Diamond Drilling:** Commence step-out diamond drilling down-plunge of the main cumulate horizon (Q1 2025)
- **Pending Assays:** Report results from 3,011 meters of pending assays (Q2 2025)
- **Independent JORC Mineral Resource Estimate:** Publish JORC-compliant Mineral Resource Estimate for Monte Alto (Q2 2025)

Forward-Looking Statements and Information

This Announcement may contain “forward-looking statements” and “forward-looking information”, including statements and forecasts which include (without limitation) expectations regarding industry growth and other trend projections, forward-looking statements about the BRE’s Projects, future strategies, results and outlook of BRE and the opportunities available to BRE. Often, but not always, forward-looking information can be identified by the use of words such as “plans”, “expects”, “is expected”, “is expecting”, “budget”, “outlook”, “scheduled”, “target”, “estimates”, “forecasts”, “intends”, “anticipates”, or “believes”, or variations (including negative variations) of such words and phrases, or state that certain actions, events or results “may”, “could”, “would”, “might”, or “will” be taken, occur or be achieved. Such information is based on assumptions and judgments of BRE regarding future events and results. Readers are cautioned that forward-looking information involves known and unknown risks, uncertainties and other factors which may cause the actual results, targets, performance or achievements of BRE to be materially different from any future results, targets, performance or achievements expressed or implied by the forward-looking information.

Forward-looking statements are not guarantees of future performance and involve known and unknown risks, uncertainties, assumptions and other important factors, many of which are beyond the control of the Company, the Directors and management of the Company. Key risk factors associated with an investment in the Company are detailed in Section 3 of the Prospectus dated 13 November 2023. These and other factors could cause actual results to differ materially from those expressed in any forward-looking statements.

Forward-looking information and statements are (further to the above) based on the reasonable assumptions, estimates, analysis and opinions of BRE made on the perception of trends, current conditions and expected developments, as well as other factors that BRE believes to be relevant and reasonable in the circumstances at the date such statements are made, but which may prove to be incorrect. Although BRE believes that the assumptions and expectations reflected in such forward-looking statements and information (including as described in this Announcement) are reasonable, readers are cautioned that this is not exhaustive of all factors which may impact on the forward-looking information.

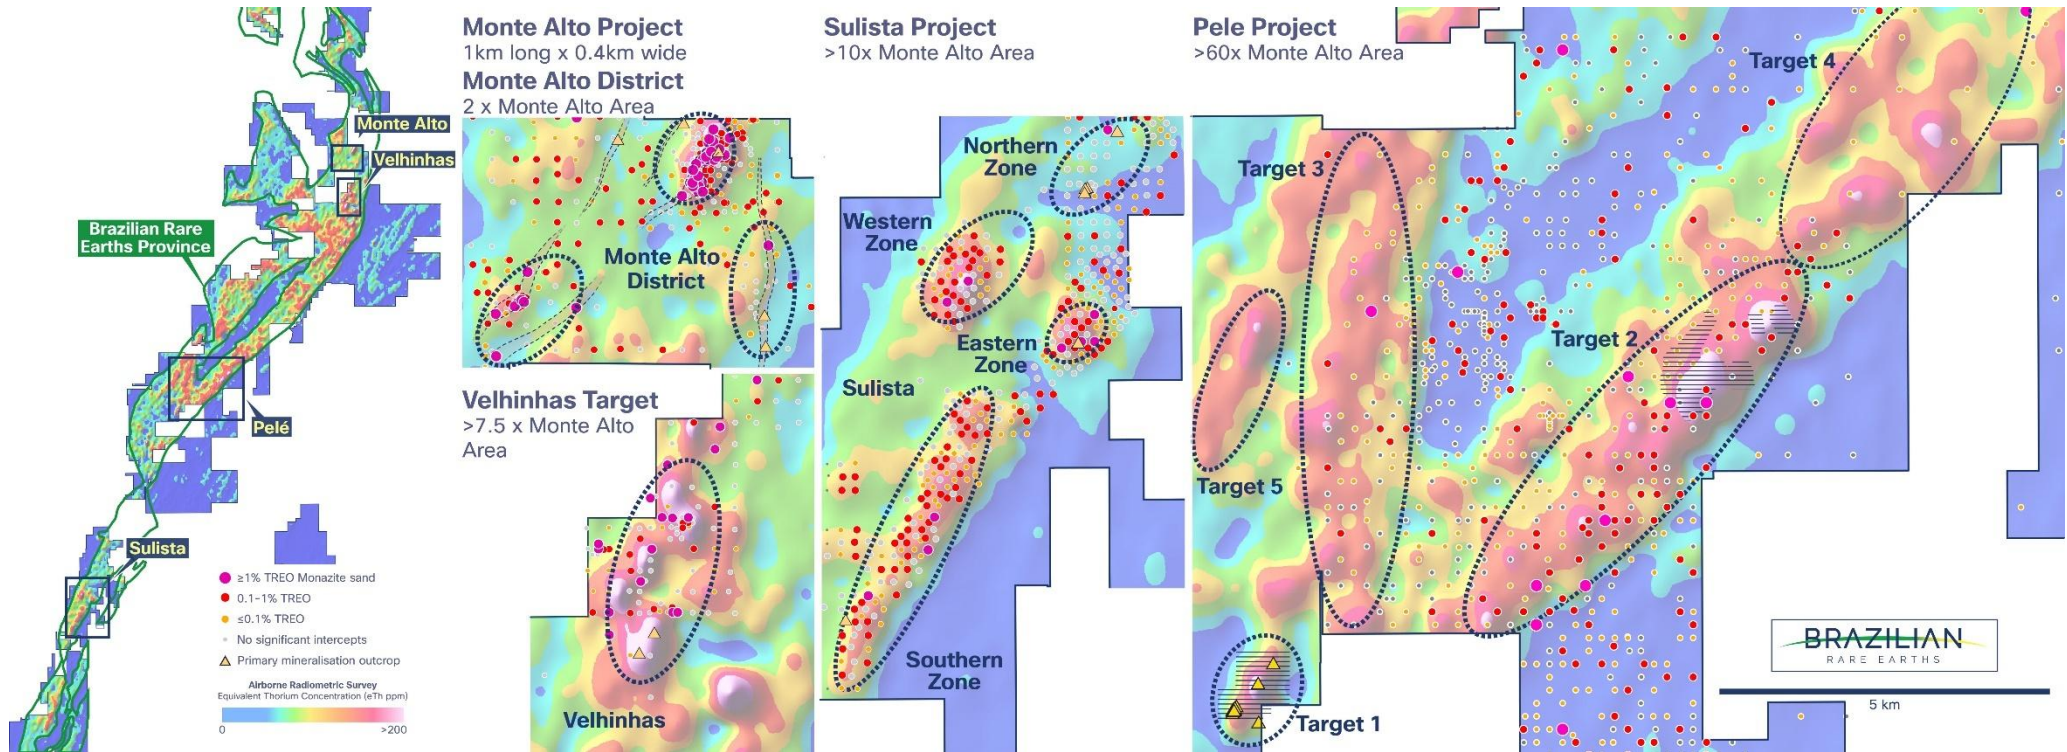

The Company cannot and does not give assurances that the results, performance or achievements expressed or implied in the forward-looking information or statements detailed in this Announcement will actually occur and prospective investors are cautioned not to place undue reliance on these forward-looking information or statements.

Forward looking statements in these materials speak only at the date of issue. Subject to any continuing obligations under applicable law or any relevant stock exchange listing rules, in providing this information the Company does not undertake any obligation to publicly update or revise any of the forward-looking statements or to advise of any change in events, conditions or circumstances on which any such statement is based.

Competent Persons Statement

The information in this announcement that relates to Exploration Results is based on, and fairly represents, information compiled or reviewed by Mr Adam Karst P.G, a Competent Person who is a registered member of the Society of Mining, Metallurgy and Exploration which is a Recognised Overseas Professional Organisation. Mr Karst is an employee of Karst Geo Solutions, LLC. Mr Karst has sufficient experience that is relevant to the style of mineralisation and types of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the Joint Ore Reserves Committee Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves. Mr. Karst consents to the inclusion in this report of the results of the matters based on his information in the form and context in which it appears

APPENDIX D: JORC Table

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections)

| Criteria | JORC Code explanation | Commentary |
|-----------------------|---|--|
| Sampling techniques | <ul style="list-style-type: none"> Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling. Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg. 'reverse circulation drilling was used to obtain 1m samples from which 3kg was pulverised to produce a 30g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg. submarine nodules) may warrant disclosure of detailed information. | <p>The reported drill results are obtained from diamond core drilling. Diamond drill holes were drilled with 3m run lengths in fresh rock and 1.5m run length in saprolite. Drill core was collected directly from a core barrel and placed in pre-labelled core trays. Run interval depths were measured and recorded. Drill core was transported to the BRE's exploration facility where it was measured for recovery, geologically logged, photographed, and marked up for sampling.</p> <p>Selected sample intervals considered lithological boundaries (i.e. sample was to, and not across, major contacts). Diamond core was HQ or NQ size. The diamond core sample intervals were a minimum of 0.5m and a maximum of 3m.</p> <p>Diamond drill core was cut using a core saw into two quarter core samples with one summited for assay and the other retained for archive. The remaining half core remained in the core tray for further testing. Cuts were made along a line drawn to ensure samples were not influenced by the distribution of mineralisation within the drill core (i.e. the cut line bisected mineralized zones). The split for assay was placed in pre-numbered sample bags for shipment to the laboratory for ICPMS analysis.</p> <p>All drilling provided a continuous sample of mineralized zone. All mineralisation that is material to this report has been directly determined through quantitative laboratory analytical techniques that are detailed in the sections below.</p> |
| Drilling techniques | <ul style="list-style-type: none"> Drill type (eg. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg. core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc). | <p>Core drilling was conducted using an I-800 DKVIII-12 rig to drill angled holes with an operational depth limit of 500m and an average depth of 155m.</p> <p>Drill core was recovered from surface to the target depth. All diamond drill holes utilized a 3.05m long single wall barrel and were collared with HQ and were transitioned to NQ once non-weathered and unoxidized bedrock was encountered. Water is used as a drilling fluid as necessary and to aid in extruding material from the core barrel.</p> <p>Oriented core was collected on selected angled drill holes using the REFLEX ACT III tool by a qualified geologist at the drill rig. The orientation data is currently being evaluated.</p> |
| Drill sample recovery | <ul style="list-style-type: none"> Method of recording and assessing core and chip sample recoveries and results assessed. | <p>The sonic and diamond core was transported from the drill site to the logging facility in covered boxes with the utmost care. Once at the logging facility, broken core was re-aligned to its original position as closely as possible. The recovered drill core was measured, and the length was divided</p> |

| | | |
|--|--|---|
| | <ul style="list-style-type: none"> Measures taken to maximise sample recovery and ensure representative nature of the samples. Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material. | <p>by the interval drilled and expressed as a percentage. This recovery data was recorded in the database.</p> <p>Recoveries for all core drilling are consistently good. There does not appear to be a relationship between sample recovery and grade or sample bias due to preferential loss or gain of fine or coarse material with these drilling and sampling methods.</p> |
| Logging | <ul style="list-style-type: none"> Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies. Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography. The total length and percentage of the relevant intersections logged. | <p>Data was collected in sufficient detail to support Mineral Resource estimation studies. All drill core was logged at the Company's exploration facility by the logging geologist. Core was photographed wet in core boxes immediately before sampling. Core photos show sample numbers, drill run lengths for material in the core box.</p> <p>Logging included qualitative determinations of primary and secondary lithology units, weathering profile unit (mottled zone, lateritic zone, saprock, saprolite, etc.) as well as colour and textural characteristics of the rock.</p> <p>GPS coordinates as well as geological logging data for all drillholes were captured in a Microsoft Excel spreadsheet and uploaded to the project database in MXDeposit. Data was collected in sufficient detail to support Mineral Resource estimation.</p> <p>All drill holes reported in this news release were logged entirely.</p> |
| Sub-sampling techniques and sample preparation | <ul style="list-style-type: none"> If core, whether cut or sawn and whether quarter, half or all core taken. If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry. For all sample types, the nature, quality and appropriateness of the sample preparation technique. Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples. Measures taken to ensure that the sampling is representative of the in-situ material collected, including for instance results for field duplicate/second-half sampling. Whether sample sizes are appropriate to the grain size of the material being sampled. | <p>Core from diamond drilling was split to obtain quarter core sub-samples for assaying. Reported diamond core sample intervals were typically 1m in length with a minimum of 0.5m and a maximum of 3m. Interval lengths considered lithological boundaries (i.e. sample was to, and not across, major contacts). To avoid selection bias, the right of core was consistently sampled and the bottom half retained in the core tray for archiving.</p> <p>Field duplicates were completed at frequency 1:20 samples to evaluate the sample collection procedures to ensure representativeness and show good reproducibility. Duplicate analyses of coarse crush and pulp material were provided by SGS.</p> <p>Core sub-samples submitted for assaying had an average weight of 1 kg. Submitted have appropriate mass to represent the material collected which includes mega-enclaves of cumulate REE-Nb-Sc-Ta-U mineralisation, microparticle to sand sized monazite grains, and ionic clay REE mineralisation.</p> |
| Quality of assay data and laboratory tests | <ul style="list-style-type: none"> The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total. For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc. Nature of quality control procedures adopted (eg. standards, blanks, | <p>Drill core samples collected by the Company were assayed by SGS Geosol in Vespasiano, Minas Gerais, Brazil, which is considered the Primary laboratory.</p> <p>Samples were initially dried at 105 degrees Celsius for 24 hours. Samples were crushed to 75% passing the 3mm fraction and the weight was recorded. The sample was reduced on a rotary splitter and then 250g to 300g of the sample was pulverized to 95% passing 75 µm. Residues were stored for check analysis or further exploration purposes.</p> |

duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.

The assay technique used for REE was Lithium Borate Fusion ICP-MS (SGS Geosol code IMS95A). This is a total analysis of the REE. Elements analysed at ppm levels were as follows:

| | | | | | | | |
|----|----|----|----|----|----|----|----|
| Ce | Co | Cs | Cu | Dy | Er | Eu | Ga |
| Gd | Hf | Ho | La | Lu | Mo | Nb | Nd |
| Ni | Pr | Rb | Sm | Sn | Ta | Tb | Th |
| Tl | Tm | U | W | Y | Yb | | |

Overlimit samples were analysed at percentage levels using SGS Geosol analysis code IMS95RS

The assay technique used for major oxides and components was Lithium Borate Fusion ICP-OES (SGS Geosol code ICP95A). This is a total analysis for the elements analysed % and ppm (Ba, V, Sr, Zn, Zr) levels as listed below:

| | | | |
|--------------------------------|-------------------------------|------------------|--------------------------------|
| Al ₂ O ₃ | Ba | CaO | Cr ₂ O ₃ |
| Fe ₂ O ₃ | K ₂ O | MgO | MnO |
| Na ₂ O | P ₂ O ₅ | SiO ₂ | Sr |
| TiO ₂ | V | Zn | Zr |

Analysis for Scandium (Sc) was made by 4-Acid ICP-AES Analysis (SGS Geosol code ICM40-FR).

Accuracy was monitored through submission of certified reference materials (CRMs) supplied by OREAS North America Inc. CRM materials (25a, 106, 147, 460 and 465) cover a range of REE grades encountered on the project. CRM 465 has an equivalent grade of approximately 10% TREO and supports reliable analysis of high grade REEE-Nb-Sc mineralisation detailed in this report. CRM were inserted within batches of core, sonic and auger drill samples, and grab samples, at a frequency of 1:20 samples.

CRMs were submitted as “blind” control samples not identifiable by the laboratory and were alternated to span the range of expected grades within a group of 100 samples.

Contamination was monitored by insertion of blank samples of coarse quartz fragments. Blanks were inserted within batches of sonic and auger drill samples, and grab samples, at a frequency of 1:40 samples. Blanks pass through the entire sample preparation stream to test for cross contamination at each stage. No laboratory contamination or bias were noticed.

Precision and sampling variance was monitored by the collection ‘Field duplicate’ samples, predominantly from mineralised intervals, at the rate of 1:20 samples. Half core was split into two ¼ core samples to make field duplicate pairs that are analysed sequentially.

| | | |
|--|---|--|
| | | <p>The adopted QA/QC protocols are acceptable for this stage of exploration. Examination of the QA/QC sample data indicates satisfactory performance of field sampling protocols and assay laboratory procedures. Levels of precision and accuracy are sufficient to allow disclosure of analysis results and their use for Mineral Resource estimation.</p> |
| <p>Verification of sampling and assaying</p> | <ul style="list-style-type: none"> • <i>The verification of significant intersections by either independent or alternative company personnel.</i> • <i>The use of twinned holes.</i> • <i>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</i> • <i>Discuss any adjustment to assay data.</i> | <p>No independent verification of significant intersections was undertaken.</p> <p>Nineteen closely spaced twin holes were drilled using a sonic drill rig to verify the auger drilling and sampling methods. There does not appear to be a systematic bias associated with auger drill method. Mean assay values obtained by augering are not likely to be higher or lower than values obtained by sonic drilling.</p> <p>All assay results are checked by the company's Principal Geologist. Logging for drillholes was directly uploaded to the project database housed in the MXDeposit system. Assay data and certificates in digital format from the laboratory are directly uploaded to the project database.</p> <p>Rare earth oxide is the industry-accepted form for reporting rare earth elements. The following calculations are used for compiling REO into their reporting and evaluation groups:</p> <p>Note that Y₂O₃ is included in the TREO, HREO and MREO calculations.</p> <p>TREO (Total Rare Earth Oxide) = La₂O₃ + CeO₂ + Pr₆O₁₁ + Nd₂O₃ + Sm₂O₃ + Eu₂O₃ + Gd₂O₃ + Tb₄O₇ + Dy₂O₃ + Ho₂O₃ + Er₂O₃ + Tm₂O₃ + Yb₂O₃ + Y₂O₃ + Lu₂O₃.</p> <p>HREO (Heavy Rare Earth Oxide) = Sm₂O₃ + Eu₂O₃ + Gd₂O₃ + Tb₄O₇ + Dy₂O₃ + Ho₂O₃ + Er₂O₃ + Tm₂O₃ + Yb₂O₃, + Y₂O₃ + Lu₂O₃.</p> <p>MREO (Magnet Rare Earth Oxide) = Nd₂O₃ + Pr₆O₁₁Pr₆O₁₁ + Tb₄O₇ + Dy₂O₃ + Gd₂O₃ + Ho₂O₃ + Sm₂O₃ + Y₂O₃.</p> <p>LREO (Light Rare Earth Oxide) = La₂O₃ + CeO₂ + Pr₆O₁₁ + Nd₂O₃.</p> <p>NdPr = Nd₂O₃ + Pr₆O₁₁.</p> <p>NdPr% of TREO = Nd₂O₃ + Pr₆O₁₁/TREO x 100.</p> <p>HREO% of TREO = HREO/TREO x 100.</p> <p>Conversion of elemental analysis (REE) to stoichiometric oxide (REO) was undertaken by spreadsheet using defined conversion factors.</p> |

| <p data-bbox="136 911 304 963"><i>Location of data points</i></p> | <ul data-bbox="331 911 1093 1066" style="list-style-type: none"> • Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation. • Specification of the grid system used. • Quality and adequacy of topographic control. | <p data-bbox="1131 866 2040 890">Diamond drill collars are located by a surveyor using RTK-GPS with centimetre scale accuracy.</p> <p data-bbox="1131 922 2089 1010">Drill hole surveying was performed on each diamond hole using a REFLEX EZ-Trac multi-shot instrument. Readings were taken every 10 to 25 meters and recorded depth, azimuth, and inclination. Projected drill hole traces show little deviation from planned orientations.</p> <p data-bbox="1131 1042 2089 1098">The accuracy of projected exploration data locations is sufficient for this stage of exploration and to support mineral resource estimation studies.</p> <p data-bbox="1131 1129 2089 1182">The grid datum used is SIRGAS 2000 UTM 24S. Topographic control is provided by an airborne LIDAR lateral resolution of 3m².</p> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| <p data-bbox="136 1190 304 1246"><i>Data spacing and distribution</i></p> | <ul data-bbox="331 1190 1059 1377" style="list-style-type: none"> • Data spacing for reporting of Exploration Results. • Whether the data spacing, and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied. • Whether sample compositing has been applied. | <p data-bbox="1131 1190 2089 1305">For selected areas at Monte Alto that host fresh rock REE-Nb-Sc-U mineralisation, the drill spacing is generally 25m to 200m along strike and down dip. This spacing is sufficient to determine continuity in geology and grade with sufficient resolution to support mineral resource estimation and targeting.</p> <p data-bbox="1131 1337 2089 1420">At all target areas laterally extensive REE enriched horizons are present in the regolith. These areas are tested by auger and sonic drilling at spacings ranging from approximately 80m to 400m in the north-south and east west directions. At Monte Alto, REE are predominantly hosted in the regolith</p> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| | | |
|---|--|---|
| | | <p>by sand sized monazite grains distributed within a central high-grade zone. This zone is tested by auger and sonic drilling at 80 m grid spacings. For all regolith mineralisation styles, the drill spacing is sufficient to establish geology and grade continuity in accordance with Inferred classification criteria.</p> <p>Composite sample grades are calculated by generating length weighted averages of assay values.</p> |
| <p><i>Orientation of data in relation to geological structure</i></p> | <ul style="list-style-type: none"> • <i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i> • <i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i> | <p>The distribution of REE in the regolith horizons is largely controlled by vertical changes within the profile. Vertical drill holes intersect these horizons perpendicularly and obtain representative samples that reflect the true width of horizontal mineralisation. In regolith, auger and sonic drill hole orientations do not result in geometrically biased interval thickness.</p> <p>The distribution of mineralisation in fresh rock at Monte Alto is controlled by steeply dipping to sub vertical mega-enclaves of monazite cumulate that strike northwest. The angled drill holes were designed and oriented with inclinations ranging from -30 to -80 degrees to intersect these bodies as perpendicular as possible within the limitations of the drill rig. Vertical SSD series holes tend to intersect mineralisation at a highly oblique angle.</p> <p>Grab samples are collected from single location points on outcropping material, or boulders/corestones, and do not represent a continuous sample along any length of the mineralised system.</p> |
| <p><i>Sample security</i></p> | <ul style="list-style-type: none"> • <i>The measures taken to ensure sample security.</i> | <p>After collection in the field, the auger and grab samples were placed in sealed plastic bags that were then placed into larger polyweave bags labelled with the sample IDs inside and transported to the Company's secure warehouse. Drill core samples were transported in their core boxes.</p> <p>A local courier transported the samples submitted for analysis to the laboratory. A copy of all waybills related to the sample forwarding was secured from the expediter.</p> <p>An electronic copy of each submission was forwarded to the laboratory to inform them of the incoming sample shipment.</p> <p>Once the samples arrived at the laboratory, the Company was notified by the laboratory manager and any non-compliance is reported.</p> <p>The laboratory did not report any issues related to the samples received.</p> |
| <p><i>Audits or reviews</i></p> | <ul style="list-style-type: none"> • <i>The results of any audits or reviews of sampling techniques and data.</i> | <p>The Company engaged the services of Telemark Geosciences to review the sampling and analysis techniques used at the Project, and to establish a "Standard Operating Procedures" manual to guide exploration.</p> <p>CSA Global Associate Principal Consultant, Peter Siegfried has toured the Company's exploration sites and facilities and conducted reviews of sampling techniques and data. The Company has addressed recommendations and feedback provided by CSA Global.</p> |

Section 2 Reporting of Exploration Results

| Criteria | JORC Code explanation | Commentary |
|---|--|---|
| <p><i>Mineral tenement and land tenure status</i></p> | <ul style="list-style-type: none"> • <i>Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.</i> • <i>The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.</i> | <p>As at 31 March 2024, the Rocha da Rocha Project comprised 261 granted exploration permits registered with Brazil's National Mining Agency and covering an area of approximately 434,835 hectares. All exploration permits are located in Bahia, Brazil and are held by the BRE's Brazilian subsidiaries directly or are to be acquired through legally binding agreements with third parties.</p> <p>All mining permits in Brazil are subject to state and landowner royalties, pursuant to article 20, § 1, of the Constitution and article 11, "b", of the Mining Code. In Brazil, the Financial Compensation for the Exploration of Mineral Resources (Compensação Financeira por Exploração Mineral - CFEM) is a royalty to be paid to the Federal Government at rates that can vary from 1% up to 3.5%, depending on the substance. It is worth noting that CFEM rates for mining rare earth elements are 2%. CFEM shall be paid (i) on the first sale of the mineral product; or (ii) when there is mineralogical mischaracterization or in the industrialization of the substance, which is which is considered "consume" of the product by the holder of the mining tenement; or (iii) when the products are exported, whichever occurs first. The basis for calculating the CFEM will vary depending on the event that causes the payment of the royalty. The landowners royalties could be subject of a transaction, however, if there's no agreement to access the land or the contract does not specify the royalties, article 11, §1, of the Mining Code sets forth that the royalties will correspond to half of the amounts paid as CFEM.</p> <p>The exploration permits in the BRE Tenements section of Table 3 (but excluding exploration permit 871.929/2022 and 871.931/2022, and also excluding the application for exploration permit 871.928/2022) are subject to an additional 2.5% royalty agreement in favour of Brazil Royalty Corp. Participações e Investimentos Ltda (BRRCP).</p> <p>Outside of the ESEC, a further 35 tenements contain approximately 165 km that falls within a State Nature Reserve (APA Caminhos Ecológicos da Boa Esperança), in which mining activities are allowed if authorized by the local environmental agency.</p> <p>In the Brazilian legal framework, mining activities within sustainable use areas are not explicitly prohibited at federal, state, or municipal levels, despite that, the zone's management authority may prohibit mining, if it deems necessary, in the zone's management plan. Activities in these areas must reconcile economic development with environmental preservation. Mining operations impacting these areas require licensing approval from the respective zone's management authority. This authorization is contingent upon conducting thorough Environmental Impact Assessment (EIA) studies. These prescribed areas do not limit mining elsewhere on the Property.</p> |

| | | |
|--|---|--|
| | | The tenements are secure and in good standing with no known impediments to obtaining a licence to operate in the area. |
| <i>Exploration done by other parties</i> | <ul style="list-style-type: none"> • <i>Acknowledgment and appraisal of exploration by other parties.</i> | <p>On the BRE Property, no previous exploration programs conducted by other parties for REEs. Between 2007 and 2011 other parties conducted exploration that is detailed in the company's prospectus and included exploratory drilling amounting to 56,919 m in 4,257 drill holes.</p> <p>On the Sulista Property, between 2013 and 2019 the project Vendors conducted exploration on the Licences that included drilling of approximately 5,000m of across 499 auger holes and approximately 1,000m of core holes.</p> <p>As of the effective date of this report, BRE is appraising the exploration data collected by other parties.</p> |
| <i>Geology</i> | <ul style="list-style-type: none"> • <i>Deposit type, geological setting and style of mineralisation.</i> | <p>The Company's tenements contain REE deposits interpreted as analogies to Ion Adsorption ionic Clay ("IAC") deposits, and regolith hosted deposits of monazite mineral grains, and primary in-situ REE-Nb-Sc mineralisation.</p> <p>The Project is hosted by the Jequié Complex, a terrain of the north-eastern São Francisco Craton, that includes the Volta do Rio Plutonic Suite of high-K ferroan ("A-type") granitoids, subordinate mafic to intermediate rocks; and thorium rich monazitic leucogranites with associated REE.</p> <p>Bedrock REE-Nb-Sc-Ta-U mineralisation is characterized by shallow to steeply dipping mega-enclaves of chevkinite and apatite-britholite cumulate mineralisation. At Monte Alto cumulate horizons are interpreted to occupy the core of a west facing anticline. The company has initiated mapping of the limited bedrock exposures at property and proposes to undertake further infill drilling to develop a model of the local geological setting.</p> <p>The regolith surrounding the REE-Nb-Sc-Ta-U mineralization is enriched in residual monazite sand and REE bearing Th-Nb-Fe-Ti-Oxides arising from weathered cumulate mineralization. More broadly, the regolith IAC mineralisation is characterised by a REE enriched lateritic zone at surface underlain by a depleted mottled zone grading into a zone of REE-accumulation in the saprolite part of the profile.</p> |
| <i>Drill hole Information</i> | <ul style="list-style-type: none"> • <i>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:</i> <ul style="list-style-type: none"> ○ <i>easting and northing of the drill hole collar</i> ○ <i>elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar</i> ○ <i>dip and azimuth of the hole</i> ○ <i>down hole length and interception depth</i> | The details related to all the diamond core drill holes presented in this Report are detailed in Appendix B and C. |

| | | |
|--|--|---|
| | <ul style="list-style-type: none"> ○ hole length. ● If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case. | |
| Data aggregation methods | <ul style="list-style-type: none"> ● In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (eg. cutting of high grades) and cut-off grades are usually Material and should be stated. ● Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low-grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail. ● The assumptions used for any reporting of metal equivalent values should be clearly stated. | <p>Downhole length weighted averaging is used to aggregate assay data from multiple samples within a reported intercept. No grade truncations or cut-off grades were applied.</p> <p>No metal equivalents values are used.</p> |
| Relationship between mineralisation widths and intercept lengths | <ul style="list-style-type: none"> ● These relationships are particularly important in the reporting of Exploration Results. ● If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. ● If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg. 'down hole length, true width not known'). | <p>In the weathered profile all intercepts reported are down hole lengths. The geometry of mineralisation is interpreted to be flat. The drilling is vertical and perpendicular to mineralisation. In the weathered profile down hole lengths correspond to true widths.</p> <p>Significant diamond drill hole intercepts in the fresh rock are reported in down hole lengths and true thickness. The distribution of mineralisation in fresh rock at Monte Alto is controlled by shallow to steeply dipping mega-enclaves of chevkinite and apatite-britholite cumulate mineralisation that dip to the northwest. The angled drill holes have inclinations ranging from -50 to -80 degrees and will tend to intersect mineralisation at moderate angle. For these holes true thickness will typically be 60%-99% of down hole thickness. In the northern and central parts of Monte Alto vertical SDD series holes tend to intersect steep to moderately dipping mineralisation at an oblique angle, for these holes true thickness will typically be 50% of down hole thickness. In the southern parts of Monte Alto vertical SDD series holes tend to intersect mineralisation perpendicularly, for these holes true thickness will typically be 90% of down hole thickness.</p> <p>Significant results in Appendix B are reported using both down hole and true thickness values.</p> |
| Diagrams | <ul style="list-style-type: none"> ● Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views. | <p>Diagrams, tables, and any graphic visualization are presented in the body of the report.</p> |
| Balanced reporting | <ul style="list-style-type: none"> ● Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced avoiding misleading reporting of Exploration Results. | <p>The report presents all drilling results that are material to the project and are consistent with the JORC guidelines. Where data may have been excluded, it is considered not material.</p> |

| | | |
|--|--|---|
| <p><i>Other substantive exploration data</i></p> | <ul style="list-style-type: none"> • <i>Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.</i> | <p>Detailed walking radiometer surveys have been completed on the target areas using a RS-230 Portable Gamma Spectrometer. In survey mode, the total Count of gamma particles Per Second (“CPS”) is recorded in real time.</p> <p>In survey mode, the total count of radioactive elements is recorded in real time. Readings are taken at waist height (approximately 1 m from the surface), the sensor can capture values in a radius of up to 1 m².</p> <p>High CPS occur in the presence of gamma releasing minerals. Throughout the Rocha da Rocha Critical Mineral Province, BRE has observed a positive correlation between CPS and thorium and REE bearing monazite. BRE has determined that gamma spectrometry is an effective method for determining the presence of REE mineralisation that is material to this report</p> |
| <p><i>Further work</i></p> | <ul style="list-style-type: none"> • <i>The nature and scale of planned further work (eg. tests for lateral extensions or depth extensions or large-scale step-out drilling).</i> • <i>Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.</i> | <p>To further develop the Monte Alto target and develop a hard-rock REE-Nb-Sc-U Mineral Resource, the Company will complete additional step-out and infill diamond and sonic core drilling to establish geological and grade continuity.</p> <p>Upcoming works aim to validate the historic drilling and assess whether or not the project may become economically feasible including metallurgical recovery, process flowsheet and optimisation. Further resource definition through additional drilling and sampling, geological mapping, and regional exploration through additional land acquisition are also planned. No forecast is made of such matters.</p> |
